Abstract

We develop a numerical code to compute gravitational waves induced by a particle moving on eccentric inclined orbits around a Kerr black hole. For such systems, the black hole perturbation method is applicable. The gravitational waves can be evaluated by solving the Teukolsky equation with a point like source term, which is computed from the stress-energy tensor of a test particle moving on generic bound geodesic orbits. In our previous papers, we computed the homogeneous solutions of the Teukolsky equation using a formalism developed by Mano, Suzuki and Takasugi and showed that we could compute gravitational waves efficiently and very accurately in the case of circular orbits on the equatorial plane. Here, we apply this method to eccentric inclined orbits. The geodesics around a Kerr black hole have three constants of motion: energy, angular momentum and the Carter constant. We compute the rates of change of the Carter constant as well as those of energy and angular momentum. This is the first time that the rate of change of the Carter constant has been evaluated accurately. We also treat the case of highly eccentric orbits with $e = 0.9$. To confirm the accuracy of our codes, several tests are performed. We find that the accuracy is only limited by the truncation of ℓ -, k - and n -modes, where ℓ is the index of the spin-weighted spheroidal harmonics, and n and k are the harmonics of the radial and polar motion, respectively. When we set the maximum of ℓ to 20, we obtain a relative accuracy of 10^{-5} even in the highly eccentric case of $e = 0.9$. The accuracy is better for lower eccentricity. Our numerical code is expected to be useful for computing templates of the extreme mass ratio inspirals, which is one of the main targets of the Laser Interferometer Space Antenna (LISA).

§1. Introduction

Gravitational radiation is one of the most important predictions resulting from general relativity. The presence of gravitational radiation has been proved indirectly through its effect on the orbital period of the Hulse-Taylor binary pulsar.¹⁾ Owing to advances in modern technology, the era of gravitational wave astronomy has almost arrived. Several ground-based interferometric gravitational wave detectors have been operated^{2)–5)} for several years. Next-generation ground-based interferometers such as advanced LIGO, advanced VIRGO and LCGT, are planned, and will be started in the near future. Research and development studies of a space-based gravitational wave observatory project, the Laser Interferometer Space Antenna (LISA),⁶⁾ are rapidly progressing. There are also proposals for laser interferometer gravitational wave antennas in space such like a DECihertz Interferometer Gravitational wave Observatory (DECIGO)⁷⁾ and a Big Bang Observer (BBO).⁸⁾ Those will be sensitive to frequencies of $10^{-2} \leq f \leq 1$ Hz.

One of the most promising sources of gravitational waves that can be detected by LISA is a compact star orbiting a supermassive black hole. Observing gravitational waves from this type of binary system, i.e., an extreme mass ratio inspiral (EMRI), we may be able to obtain information on the central black hole's spacetime such as the mass, spin of the black hole and the mass distribution of compact objects in the center of the galaxy. To extract the physical information of EMRI from observational data obtained by the detectors, we have to compute the theoretical waveforms with a phase accuracy within one cycle over the total number of cycles. LISA is sensitive to gravitational waves around 10^{-2} Hz. When the observation of LISA is performed for one year, the total number of cycles of waves is $\sim 10^5$. Thus, to analyze one year of data obtained from LISA, we need theoretical waveforms that are accurate to 10^{-5} .

The dynamics of EMRI is accurately modeled as a point particle of small mass moving around a Kerr black hole. Therefore, gravitational waves from EMRI can be evaluated using black hole perturbation theory, which was originally developed as a metric perturbation theory for a black hole spacetime. For nonrotating (Schwarzschild) black holes, a single master equation for the metric perturbation was derived by Regge and Wheeler for the odd-parity parts,⁹⁾ and later by Zerilli for the even-parity parts.¹⁰⁾ These equations are remarkably simple, separable, hyperbolic equations with a potential term. For rotating black holes, at present, there are no simple decoupled equations for metric coefficients. Instead the perturbed geometry must be analyzed by the equations derived by Teukolsky using gauge-invariant variables corresponding to some tetrad components of the perturbed Weyl curvature.¹¹⁾

Using this Teukolsky formalism, there have been many numerical computations of gravitational waves induced by a point particle. See Chandrasekhar¹²⁾ and Nakamura *et al.*,¹³⁾ for reviews and for references on earlier papers. For simple orbits such as circular or equatorial orbits around a black hole, an accuracy of 10^{-5} has been achieved, which may be sufficient to detect gravitational waves. Computations of gravitational waves induced by a particle moving on eccentric nonequatorial orbits are now available.¹⁴⁾ However, a large amount of computation time is needed and the results have only a few orders of accuracy.

Furthermore, it has been pointed out that EMRIs radiating gravitational waves within the LISA band have high eccentricities.¹⁵⁾ So far, the gravitational energy flux has been computed only for orbits with eccentricity less than 0.7. This is primarily due to the low numerical accuracy and high computational time at the high-frequency modes. In the Teukolsky formalism in the frequency domain, when we treat a large eccentricity and large inclination angle, we need to compute a large number of harmonics corresponding to the radial and polar motion. Thus, the computation time becomes a serious problem. It is thus desirable to develop more efficient and more accurate numerical codes.

In the Kerr spacetime, there are three constants of motion of a geodesic: the energy, angular momentum and Carter constant. Using the conservation law, we can evaluate the rates of change of the energy and angular momentum of a particle due to the emission of gravitational waves. In contrast, the rate of change of the Carter constant cannot be derived from the conservation law. Mino proposed a method to evaluate the average rates of change of the three constants including the Carter constant¹⁶⁾ under an adiabatic approximation. He showed that the average rates of change can be evaluated using the radiative field instead of the retarded field. Using Mino's method, Drasco *et al.*¹⁷⁾ derived simplified version of his formula for the case of a scalar field. Sago *et al.*¹⁸⁾ developed Mino's method further, giving a simplified version of his formula. Applying their new scheme, they gave explicit analytic formulas for the rates of change of constants when a particle moves on slightly eccentric and slightly inclined orbits.¹⁹⁾ Ganz *et al.* extended this computation to the case when a particle moves on slightly eccentric and arbitrarily inclined orbits.²⁰⁾ However, these two results are based on the assumption of small eccentricity and the post-Newtonian approximation to the order $O((v/c)^5)$.

In this paper, we compute the rates of change of the three constants of motion, including the Carter constant, induced by a particle moving on eccentric and inclined orbits around a Kerr black hole without assuming small eccentricities, small inclination angles or low velocity. This is the first time that the rate of change of the Carter constant has been computed accurately using an adiabatic approximation. Drasco and Hughes²¹⁾ computed the rate of change of the Carter constant assuming that the inclination angle does not change. However,

this assumption holds only approximately, rather than exactly.

To treat cases of large eccentricity and inclination angle, we introduce various methods. The numerical method used to compute the homogeneous solution of the Teukolsky equation is based on that of Fujita and Tagoshi,^{(22), (23)} in which the Mano-Suzuki-Takasugi formalism⁽²⁴⁾ is used. However, since only circular, equatorial orbits are treated in these works, we extend the method so that we can compute the homogeneous solutions efficiently in eccentric and inclined cases. For the source term, we introduce analytical expressions for the radial and polar motion to achieve high accuracy.

The paper is organized as follows. In § 2, we summarize the details of the method for computing the gravitational waves from EMRIs using black hole perturbation theory. In § 3, we explain our numerical methods. In § 4, we discuss the peaks of radial and polar modes briefly then we derive the rates of change of the three constants of motion for highly eccentric orbits. Next, we verify our code using the Schwarzschild case and by comparison with analytical post-Newtonian expressions. Section 5 is devoted to a summary and discussion. In the Appendices, some detailed formulas are given. Throughout this paper we use units with $c = G = 1$.

§2. Formulas for the rate of change due to gravitational wave emission

In the Teukolsky formalism, the gravitational perturbation of a Kerr black hole is described in terms of the Newman-Penrose variables, Ψ_0 and Ψ_4 , which satisfy the master equation. The Weyl scalar Ψ_4 is related to the amplitude of the gravitational wave at infinity as

$$\Psi_4 \rightarrow \frac{1}{2}(\ddot{h}_+ - i\ddot{h}_\times), \text{ for } r \rightarrow \infty. \quad (2.1)$$

The master equation for Ψ_4 can be separated into radial and angular parts if we expand Ψ_4 in Fourier harmonic modes as

$$\rho^{-4}\Psi_4 = \sum_{\ell m} \int_{-\infty}^{\infty} d\omega e^{-i\omega t + im\varphi} {}_{-2}S_{\ell m}^{a\omega}(\theta) R_{\ell m\omega}(r), \quad (2.2)$$

where $\rho = (r - ia \cos \theta)^{-1}$, the angular function ${}_{-2}S_{\ell m}^{a\omega}(\theta)$ is the spin-weighted spheroidal harmonic with spin $s = -2$, and M and aM are the mass and angular momentum of the black hole, respectively. The radial function $R_{\ell m\omega}(r)$ satisfies the radial Teukolsky equation,

$$\Delta^2 \frac{d}{dr} \left(\frac{1}{\Delta} \frac{dR_{\ell m\omega}}{dr} \right) - V(r) R_{\ell m\omega} = T_{\ell m\omega}, \quad (2.3)$$

where $\Delta = r^2 - 2Mr + a^2$. The potential term $V(r)$ is given as

$$V(r) = -\frac{K^2 - 2is(r - M)K}{\Delta} - 4is\omega r + \lambda, \quad (2.4)$$

where $K = (r^2 + a^2)\omega - ma$ and λ is the eigenvalue of $_{-2}S_{\ell m}^{a\omega}(\theta)$.

We solve the radial Teukolsky equation by using the Green function method. The solution of the Teukolsky equation with a purely outgoing property at infinity and a purely ingoing property at the horizon becomes

$$R_{\ell m \omega}(r) = \frac{1}{W_{\ell m \omega}} \left\{ R_{\ell m \omega}^{\text{up}}(r) \int_{r_+}^r dr' R_{\ell m \omega}^{\text{in}} T_{\ell m \omega} \Delta^{-2} + R_{\ell m \omega}^{\text{in}}(r) \int_r^\infty dr' R_{\ell m \omega}^{\text{up}} T_{\ell m \omega} \Delta^{-2} \right\}, \quad (2.5)$$

where the Wronskian $W_{\ell m \omega}$ is given as

$$W_{\ell m \omega} = 2i\omega C_{\ell m \omega}^{\text{trans}} B_{\ell m \omega}^{\text{inc}}, \quad (2.6)$$

and where $R_{\ell m \omega}^{\text{in/up}}(r)$ satisfy ingoing/outgoing wave conditions at the horizon/infinity. The asymptotic forms of $R_{\ell m \omega}^{\text{in/up}}(r)$ are expressed as

$$\begin{aligned} R_{\ell m \omega}^{\text{in}} &\rightarrow \begin{cases} B_{\ell m \omega}^{\text{trans}} \Delta^2 e^{-iPr^*} & \text{for } r \rightarrow r_+, \\ r^3 B_{\ell m \omega}^{\text{ref}} e^{i\omega r^*} + r^{-1} B_{\ell m \omega}^{\text{inc}} e^{-i\omega r^*} & \text{for } r \rightarrow \infty, \end{cases} \\ R_{\ell m \omega}^{\text{up}} &\rightarrow \begin{cases} C_{\ell m \omega}^{\text{up}} e^{iPr^*} + \Delta^2 C_{\ell m \omega}^{\text{ref}} e^{-iPr^*} & \text{for } r \rightarrow r_+, \\ r^3 C_{\ell m \omega}^{\text{trans}} e^{i\omega r^*} & \text{for } r \rightarrow \infty, \end{cases} \end{aligned} \quad (2.7)$$

where $P = \omega - ma/2Mr_+$ and r^* is the tortoise coordinate defined as

$$r^* = r + \frac{2Mr_+}{r_+ - r_-} \ln \frac{r - r_+}{2M} - \frac{2Mr_-}{r_+ - r_-} \ln \frac{r - r_-}{2M}, \quad (2.8)$$

with $r_\pm = M \pm \sqrt{M^2 - a^2}$.

The asymptotic property of the solution at the horizon is expressed as

$$R_{\ell m \omega}(r \rightarrow r_+) = \frac{B_{\ell m \omega}^{\text{trans}} \Delta^2 e^{-iPr^*}}{2i\omega C_{\ell m \omega}^{\text{trans}} B_{\ell m \omega}^{\text{inc}}} \int_{r_+}^\infty dr' R_{\ell m \omega}^{\text{up}} T_{\ell m \omega} \Delta^{-2} \equiv Z_{\ell m \omega}^{\text{H}} \Delta^2 e^{-iPr^*}. \quad (2.9)$$

The solution at infinity is expressed as

$$R_{\ell m \omega}(r \rightarrow \infty) = \frac{r^3 e^{i\omega r^*}}{2i\omega B_{\ell m \omega}^{\text{inc}}} \int_{r_+}^\infty dr' R_{\ell m \omega}^{\text{in}} T_{\ell m \omega} \Delta^{-2} \equiv Z_{\ell m \omega}^\infty r^3 e^{i\omega r^*}. \quad (2.10)$$

Using the formula of the source term $T_{\ell m \omega}$,²⁵⁾ $Z_{\ell m \omega}^{\infty, \text{H}}$ are expressed as

$$\begin{aligned} Z_{\ell m \omega}^{\text{H}} &= \frac{\mu B_{\ell m \omega}^{\text{trans}}}{2i\omega C_{\ell m \omega}^{\text{trans}} B_{\ell m \omega}^{\text{inc}}} \int_{-\infty}^\infty dt e^{i\omega t - im\phi(t)} \mathcal{I}_{\ell m \omega}^{\text{H}}[r(t), \theta(t)], \\ Z_{\ell m \omega}^\infty &= \frac{\mu}{2i\omega B_{\ell m \omega}^{\text{inc}}} \int_{-\infty}^\infty dt e^{i\omega t - im\phi(t)} \mathcal{I}_{\ell m \omega}^\infty[r(t), \theta(t)], \end{aligned} \quad (2.11)$$

where

$$\begin{aligned}
\mathcal{I}_{\ell m \omega}^{\text{H}} &= \left[R_{\ell m \omega}^{\text{up}} \{A_{nn0} + A_{\bar{m}n0} + A_{\bar{m}\bar{m}0}\} \right. \\
&\quad \left. - \frac{dR_{\ell m \omega}^{\text{up}}}{dr} \{A_{\bar{m}n1} + A_{\bar{m}\bar{m}1}\} + \frac{d^2 R_{\ell m \omega}^{\text{up}}}{d^2 r} A_{\bar{m}\bar{m}2} \right]_{r=r(t), \theta=\theta(t)}, \\
\mathcal{I}_{\ell m \omega}^{\infty} &= \left[R_{\ell m \omega}^{\text{in}} \{A_{nn0} + A_{\bar{m}n0} + A_{\bar{m}\bar{m}0}\} \right. \\
&\quad \left. - \frac{dR_{\ell m \omega}^{\text{in}}}{dr} \{A_{\bar{m}n1} + A_{\bar{m}\bar{m}1}\} + \frac{d^2 R_{\ell m \omega}^{\text{in}}}{d^2 r} A_{\bar{m}\bar{m}2} \right]_{r=r(t), \theta=\theta(t)}, \tag{2.12}
\end{aligned}$$

where A_{nn0} and other terms are given in Appendix A.

The function $\mathcal{I}_{\ell m \omega}^{\infty, \text{H}}[r(t), \theta(t)]$ is constructed from the source term of the Teukolsky equation and depends on the orbital worldline of the star perturbing the black hole spacetime. If the trajectory of a compact star is eccentric and inclined from the equatorial plane, it is not easy to evaluate Eq. (2.11). This is because the radial and polar motion are coupled in the observer time variable t . This problem can be solved by introducing a new time variable λ defined as $d\lambda = d\tau/\Sigma$, where $\Sigma = r^2 + a^2 \cos^2 \theta$.^{16), 26)} The geodesic equations become

$$\left(\frac{dr}{d\lambda} \right)^2 = [(r^2 + a^2)\mathcal{E} - a\mathcal{L}_z]^2 - \Delta[r^2 + (\mathcal{L}_z - a\mathcal{E})^2 + \mathcal{C}] \equiv R(r), \tag{2.13}$$

$$\begin{aligned}
\left(\frac{d \cos \theta}{d\lambda} \right)^2 &= \mathcal{C} - (\mathcal{C} + a^2(1 - \mathcal{E}^2) + \mathcal{L}_z^2) \cos^2 \theta + a^2(1 - \mathcal{E}^2) \cos^4 \theta \\
&\equiv \Theta(\cos \theta), \tag{2.14}
\end{aligned}$$

$$\frac{d\phi}{d\lambda} = \Phi_r(r) + \Phi_\theta(\cos \theta) - a\mathcal{E}, \tag{2.15}$$

$$\frac{dt}{d\lambda} = T_r(r) + T_\theta(\cos \theta) + a\mathcal{L}_z, \tag{2.16}$$

where

$$\begin{aligned}
\Phi_r(r) &\equiv \frac{a}{\Delta} [\mathcal{E}(r^2 + a^2) - a\mathcal{L}_z], \quad \Phi_\theta(\cos \theta) \equiv \frac{\mathcal{L}_z}{1 - \cos^2 \theta}, \\
T_r(r) &\equiv \frac{r^2 + a^2}{\Delta} [\mathcal{E}(r^2 + a^2) - a\mathcal{L}_z], \quad T_\theta(\cos \theta) \equiv -a^2\mathcal{E}(1 - \cos^2 \theta),
\end{aligned}$$

and $\mathcal{E}$, $\mathcal{L}_z$ and $\mathcal{C}$ are the energy, the z -component of the angular momentum and the Carter constant per unit mass, respectively. The equations of radial and polar motion are decoupled in Eqs. (2.13) and (2.14). For the bound orbits, $r(\lambda)$ and $\theta(\lambda)$ become periodic functions that are independent of each other. The fundamental periods for the radial and polar motion, Λ_r and Λ_θ , are defined as

$$\Lambda_r = 2 \int_{r_{\min}}^{r_{\max}} \frac{dr}{\sqrt{R(r)}}, \quad \Lambda_\theta = 4 \int_0^{\cos \theta_{\min}} \frac{d \cos \theta}{\sqrt{\Theta(\cos \theta)}}. \tag{2.17}$$

The angular frequencies of the radial and polar motion become

$$\Upsilon_r = \frac{2\pi}{\Lambda_r}, \quad \Upsilon_\theta = \frac{2\pi}{\Lambda_\theta}. \quad (2.18)$$

Explicit expressions for Υ_r and Υ_θ are given in Appendix B.

We define the angle variables as $w_r = \Upsilon_r \lambda$ and $w_\theta = \Upsilon_\theta \lambda$. The functions that depend only on r or θ become periodic functions with respect to w_r or w_θ , respectively, with period 2π .

We expand the right-hand sides of Eqs. (2.15) and (2.16) into Fourier series,

$$\frac{dt}{d\lambda} = \sum_{k,n} T_{k,n} e^{-ik\Upsilon_r \lambda} e^{-in\Upsilon_\theta \lambda}, \quad (2.19)$$

$$\frac{d\phi}{d\lambda} = \sum_{k,n} \Phi_{k,n} e^{-ik\Upsilon_r \lambda} e^{-in\Upsilon_\theta \lambda}, \quad (2.20)$$

where

$$T_{k,n} = \frac{1}{(2\pi)^2} \int_0^{2\pi} dw_r \int_0^{2\pi} dw_\theta (T_r(r) + T_\theta(\cos \theta) + a\mathcal{L}_z) e^{ikw_r} e^{inw_\theta}, \quad (2.21)$$

$$\Phi_{k,n} = \frac{1}{(2\pi)^2} \int_0^{2\pi} dw_r \int_0^{2\pi} dw_\theta (\Phi_r(r) + \Phi_\theta(\cos \theta) - a\mathcal{E}) e^{ikw_r} e^{inw_\theta}. \quad (2.22)$$

$$(2.23)$$

Since $T_{k,n} = 0$ and $\Phi_{k,n} = 0$ in the case of $k \neq 0$ and $n \neq 0$, we have

$$\frac{dt}{d\lambda} = \Gamma + \sum_{k \neq 0} T_{k,0} e^{-ikw_r} + \sum_{n \neq 0} T_{0,n} e^{-inw_\theta}, \quad (2.24)$$

$$\Gamma \equiv T_{00}$$

$$= \Upsilon_{t(r)} + \Upsilon_{t(\theta)} + a\mathcal{L}_z, \quad (2.25)$$

$$\frac{d\phi}{d\lambda} = \Upsilon_\phi + \sum_{k \neq 0} \Phi_{k,0} e^{-ikw_r} + \sum_{n \neq 0} \Phi_{0,n} e^{-inw_\theta}, \quad (2.26)$$

$$\Upsilon_\phi \equiv \Phi_{00}$$

$$= \Upsilon_{\phi(r)} + \Upsilon_{\phi(\theta)} - a\mathcal{E}, \quad (2.27)$$

where

$$\begin{aligned} \Upsilon_{t(r)} &= \frac{1}{2\pi} \int_0^{2\pi} dw_r T_r, & \Upsilon_{t(\theta)} &= \frac{1}{2\pi} \int_0^{2\pi} dw_\theta T_\theta, \\ \Upsilon_{\phi(r)} &= \frac{1}{2\pi} \int_0^{2\pi} dw_r \Phi_r, & \Upsilon_{\phi(\theta)} &= \frac{1}{2\pi} \int_0^{2\pi} dw_\theta \Phi_\theta. \end{aligned} \quad (2.28)$$

Since $T_{k,n} = 0$ for $k \neq 0$ and $n \neq 0$, we need to compute $T_{k,0}$, $T_{0,n}$, $\Phi_{k,0}$ and $\Phi_{0,n}$, which can be easily obtained from a one-dimensional Fourier transformation. We obtain the functions $t(\lambda)$ and $\phi(\lambda)$ from the following formulas:

$$t(\lambda) = \Gamma\lambda + \sum_{k \neq 0} \frac{iT_{k,0}}{k\Upsilon_r} e^{-ikw_r} + \sum_{n \neq 0} \frac{iT_{0,n}}{n\Upsilon_\theta} e^{-inw_\theta}, \quad (2.29)$$

$$\phi(\lambda) = \Upsilon_\phi\lambda + \sum_{k \neq 0} \frac{i\Phi_{k,0}}{k\Upsilon_r} e^{-ikw_r} + \sum_{n \neq 0} \frac{i\Phi_{0,n}}{n\Upsilon_\theta} e^{-inw_\theta}. \quad (2.30)$$

The two variables, Γ and Υ_ϕ , represent the average rates of change of t and ϕ as functions of λ , respectively.

When we consider the bound orbits of a point particle using λ , the amplitude of the partial wave $Z_{\ell m \omega}^{\infty, H}$, defined in Eq. (2.11), can be expanded by using a Fourier series as

$$Z_{\ell m \omega}^{\infty, H} \equiv \sum_{kn} \tilde{Z}_{\ell m kn}^{\infty, H} \delta(\omega - \omega_{mkn}), \quad (2.31)$$

where

$$\tilde{Z}_{\ell m kn}^{\infty, H} = \frac{1}{(2\pi)^2} \int_0^{2\pi} dw_\theta \int_0^{2\pi} dw_r e^{i(kw_\theta + nw_r)} Z_{\ell m \omega_{mkn}}^{\infty, H} [r(w_r), \theta(w_\theta)] \quad (2.32)$$

and

$$\omega_{mkn} \equiv (m\Upsilon_\phi + k\Upsilon_\theta + n\Upsilon_r)/\Gamma. \quad (2.33)$$

Using these functions, the gravitational waveform at infinity is expressed as

$$h_+ - ih_\times = -\frac{2}{r} \sum_{\ell m kn} \frac{\tilde{Z}_{\ell m kn}^\infty}{\omega_{mkn}^2} \frac{-2S_{\ell m}^{a\omega_{mkn}}(\theta)}{\sqrt{2\pi}} e^{i\omega_{mkn}(r^* - t) + im\phi}. \quad (2.34)$$

Moreover, the time-averaged rates of change for the three constants of motion due to the emission of gravitational waves are expressed as^{(16), (18), (19)}

$$\left\langle \frac{d\mathcal{E}}{dt} \right\rangle = -\mu^{-1} \sum_{\ell m kn} \frac{1}{4\pi\omega_{mkn}^2} \left(\left| \tilde{Z}_{\ell m kn}^\infty \right|^2 + \alpha_{\ell m kn} \left| \tilde{Z}_{\ell m kn}^H \right|^2 \right), \quad (2.35)$$

$$\left\langle \frac{d\mathcal{L}_z}{dt} \right\rangle = -\mu^{-1} \sum_{\ell m kn} \frac{m}{4\pi\omega_{mkn}^3} \left(\left| \tilde{Z}_{\ell m kn}^\infty \right|^2 + \alpha_{\ell m kn} \left| \tilde{Z}_{\ell m kn}^H \right|^2 \right), \quad (2.36)$$

$$\left\langle \frac{d\mathcal{C}}{dt} \right\rangle = \left\langle \frac{d\mathcal{Q}}{dt} \right\rangle - 2(a\mathcal{E} - \mathcal{L}_z) \left(a \left\langle \frac{d\mathcal{E}}{dt} \right\rangle - \left\langle \frac{d\mathcal{L}_z}{dt} \right\rangle \right), \quad (2.37)$$

$$\begin{aligned} \left\langle \frac{d\mathcal{Q}}{dt} \right\rangle &= 2\Upsilon_{t(r)} \left\langle \frac{d\mathcal{E}}{dt} \right\rangle - 2\Upsilon_{\phi(r)} \left\langle \frac{d\mathcal{L}_z}{dt} \right\rangle \\ &\quad + \mu^{-2} \sum_{\ell m kn} \frac{n\Upsilon_r}{2\pi\omega_{mkn}^3} \left(\left| \tilde{Z}_{\ell m kn}^\infty \right|^2 + \alpha_{\ell m kn} \left| \tilde{Z}_{\ell m kn}^H \right|^2 \right), \end{aligned} \quad (2.38)$$

Fig. 1. Plots of generic bound geodesic orbits with eccentricity $e = 0.7$, semilatus rectum $p = 10M$ and inclination angle $\theta_{\text{inc}} = 45^\circ$. The black hole's spin is set to $a = 0.9M$. The left figure is expressed using a Cartesian coordinate system. The right figure is expressed by using a corotational system, defined as Eq. (3.2).

Fig. 2. The left figure is the projected image of right figure in Fig. 1. The right figure is the projected image of the same figure to the $Z = Y \tan \theta_{\text{inc}}$ plane. Here the coordinates (X', Y') are defined as $X' = X$ and $Y' = Y \cos \theta_{\text{inc}} + Z \sin \theta_{\text{inc}}$. The left figure shows that the orbit almost stays on the plane inclined by θ_{inc} from the equatorial plane.

where

$$\alpha_{\ell m k n} = \frac{256(2Mr_+)^5 P(P^2 + 4\epsilon^2)(P^2 + 16\epsilon^2)\omega_{mkn}^3}{C_{\ell m k n}^{\text{TS}}}, \quad (2.39)$$

where $\epsilon = \sqrt{M^2 - a^2}/4Mr_+$, $P = \omega_{mkn} - ma/(2Mr_+)$, $r_+ = M + \sqrt{M^2 - a^2}$ is the location of the event horizon and $C_{\ell m k n}^{\text{TS}}$ is the Teukolsky-Starobinsky constant.²⁷⁾ Here $\langle \dots \rangle$ represents the time average.

§3. Numerical methods

In this section, we discuss the numerical method used to compute $\tilde{Z}_{lmkn}^{\infty/H}$, Eq. (2.32). The numerical computation is divided into four parts: geodesics, homogeneous solutions, the integration of Eq. (2.32) and the mode summation in Eqs. (2.35)–(2.38). In the following subsections, we explain the method for obtaining the geodesic and homogeneous solutions. The numerical integration of Eq. (2.32) and the mode summation are explained in § 4.

3.1. Geodesics

Geodesics around a Kerr black hole are completely specified by the three constants of motion, $(\mathcal{E}, \mathcal{L}_z, \mathcal{C})$. Instead of using these three constants, it is convenient to introduce three orbital parameters: eccentricity e , semilatus rectum p and inclination angle θ_{inc} which are defined in Eq. (B.3). There is a one-to-one correspondence between the orbital parameters $(p, e, \theta_{\text{inc}})$ and $(\mathcal{E}, \mathcal{L}_z, \mathcal{C})$.^{21), 28)}

Our method of computing geodesic motion is summarized as follows. We specify three orbital parameters, $(p, e, \theta_{\text{inc}})$. We first compute the constants of motion, $\mathcal{E}$, $\mathcal{L}_z$ and $\mathcal{C}$, which correspond to $(p, e, \theta_{\text{inc}})$. We then compute the orbital frequencies of the radial and polar motion, Υ_r and Υ_θ . We find that the solutions of the r and θ components of the geodesic equations are expressed in terms of Jacobi elliptic functions, which can be easily computed numerically (see Appendix B). This enables us to evaluate the bound orbits accurately. We have not confirmed whether this method is faster than the numerical integration methods when the same accuracy is required. However, since we need to compute the geodesic motion only once, its computation time is negligible compared with the total computation time. Thus, we adopt this method. The r and θ components of coordinates and velocity of the particle, $r(w_r)$, $[dr/d\lambda](w_r)$, $[\cos\theta](w_\theta)$ and $[d\cos\theta/d\lambda](w_\theta)$, are respectively expressed using w_r and w_θ analytically.

The t and ϕ components of the solution of the geodesic equations can be obtained using the Fourier series expansion, Eqs. (2.29) and (2.30). We truncate the Fourier series expansion at a certain frequency. Since the convergence of the Fourier series is rapid, as mentioned in Ref. 21), this does not cause serious problems. Explicit expressions for orbital frequencies and the solutions of radial and polar motion are given in Appendix B.

Here we demonstrate a geodesic orbit computed using our code. We start an orbit at $(t, r, \theta, \phi) = (0, p/(1+e), 0, 0)$, and end it after several oscillation periods of radial and polar motion. In Fig. 1, we plot the orbit on two different coordinate systems. The left figure of Fig. 1 is expressed using the Cartesian coordinate system (t, x, y, z) defined as

$$t = t, \quad x = r \sin\theta \cos\phi, \quad y = r \sin\theta \sin\phi, \quad z = r \cos\theta. \quad (3.1)$$

This figure indicates the well-known fact that generic geodesic orbits around a Kerr black hole are complicated. To understand the physical meaning of the orbital parameters p , e and θ_{inc} , it is useful to express the orbit using the corotational coordinate system (t, X, Y, Z) defined as

$$t = t, \quad X = x \cos(\Upsilon_{\text{pre}}\lambda) - y \sin(\Upsilon_{\text{pre}}\lambda), \quad Y = x \sin(\Upsilon_{\text{pre}}\lambda) + y \cos(\Upsilon_{\text{pre}}\lambda), \quad Z = z, \quad (3.2)$$

where the precession frequency, Υ_{pre} , is defined as $\Upsilon_{\text{pre}} := \Upsilon_{\theta} - \Upsilon_{\phi}$. The right figure in Fig. 1 is expressed in the corotational coordinate system. The left figure in Fig. 2 is a plot of the orbits projected onto the $X = 0$ plane. This figure shows that the particle almost remains on the $Z = Y \tan \theta_{\text{inc}}$ plane. In fact, the orbit around a Schwarzschild black hole is exactly on this plane. On the other hand, when the parameter p becomes small and the particle approaches the horizon, it becomes impossible to define such an approximate orbital plane. In such a case, it is not appropriate to call the parameter θ_{inc} the inclination angle.

The right figure in Fig. 2 is the projected image onto the $Z = Y \tan \theta_{\text{inc}}$ plane. The minimum and maximum distances from the origin, r_{min} and r_{max} , are $r_{\text{min}} = p/(1 + e)$ and $r_{\text{max}} = p/(1 - e)$. In this sense, e and p are called the eccentricity and semilatus rectum, respectively.

3.2. Homogeneous solutions

Mano, Suzuki and Takasugi²⁴⁾ (MST) formulated a method to express homogeneous solutions of the Teukolsky equation, $R_{\ell m \omega}^{\text{in}}$ and $R_{\ell m \omega}^{\text{up}}$, in series of hypergeometric functions or Coulomb wave functions. Fujita and Tagoshi^{22), 23)} applied the MST method to the numerical computation of gravitational waves from a particle moving on circular, equatorial orbits around a black hole. To read off the asymptotic amplitudes such as B^{inc} and B^{ref} , we usually have to numerically integrate the homogeneous Teukolsky equation from r_+ to a large radius. In the MST formalism, on the other hand, the analytical forms of these asymptotic amplitudes of the homogeneous Teukolsky equation are given. We can evaluate the asymptotic amplitude very accurately. Furthermore, since the convergence of the series of hypergeometric functions is fast, we can obtain the homogeneous solutions themselves very accurately. In this paper, since we treat eccentric orbits, we need to evaluate the homogeneous solutions at many radial points. Although the convergence of the series of hypergeometric functions or Coulomb wave functions is very fast, the computation time required to evaluate these series is not negligible. We thus use the method of successive Taylor series expansions.

We first compute a homogeneous solution at a radius r , where $r_{\text{min}} \leq r \leq r_{\text{max}}$, using the series of hypergeometric functions. This gives a very accurate boundary value of the solution. We then compute the homogeneous solution at $r + h$ using the Taylor series expansion

around r . The n th derivative of the homogeneous solution at radius r is evaluated from the recurrence relations derived by differentiating the homogeneous Teukolsky equation. The relative error of the Taylor series expansion is estimated as $(d^n R_{\ell m \omega}^{\text{in/up}}(r)/dr^n)h^n/n!/R_{\ell m \omega}^{\text{in/up}}(r)$. We adjust n and h to obtain a relative error $\sim 10^{-15}$. Next, we repeat the Taylor series expansion around $r + h$ to obtain the homogeneous solution near $r + h$. In this way, we obtain $R_{\ell m \omega}^{\text{in/up}}(r)$ for all radii.

The Taylor series expansion is used to solve ordinary differential equations when high accuracy is required. The Taylor series method in Ref. 29) is faster than the standard numerical integration methods when the required accuracy is better than 10^{-6} . We adopt the Taylor series method since we aim to develop a highly accurate code. We confirmed that this method gives accurate results and is much faster than using the hypergeometric series expansion. However, we have not compared the computing time of the Taylor series method with that of the standard numerical integration method by setting the same accuracy. The use of the numerical integration method together with the MST formalism may be useful for reducing the computation time when the required accuracy is not very stringent.

The spin-weighted spheroidal harmonics, $_{-2}S_{\ell m}^{a\omega}(\theta)$, are evaluated using a series of Jacobi polynomials. The details of the numerical method are described in Ref. 22). Although it should be possible to use the Taylor series method for the spin-weighted spheroidal harmonics, we have not attempted this yet.

§4. Results

4.1. Energy spectrum

In this section, we compute the rates of change of the three constants of motion, including the Carter constant.

We use the trapezium rule to compute the integral, Eq. (2.32). This is because the integrand is a periodic function. It is well known that if a periodic function is integrated over one period, the trapezium rule is a suitable method for numerical integration.

The MST formalism can be applied only for the case that the frequency is positive, $\omega > 0$. The mode summation in Eq. (2.35) is performed using the following equations:

$$\left\langle \frac{d\mathcal{E}}{dt} \right\rangle_{\text{GW}}^{\infty} = 2 \sum_{\ell=2}^{\infty} \sum_{m=-\ell}^{\ell} \sum_{k=-\infty}^{\infty} \sum_{n=n_0}^{\infty} \left\langle \frac{d\mathcal{E}_{\ell m k n}}{dt} \right\rangle_{\text{GW}}^{\infty}, \quad (4.1)$$

$$\left\langle \frac{d\mathcal{E}}{dt} \right\rangle_{\text{GW}}^{\text{H}} = 2 \sum_{\ell=2}^{\infty} \sum_{m=-\ell}^{\ell} \sum_{k=-\infty}^{\infty} \sum_{n=n_0}^{\infty} \left\langle \frac{d\mathcal{E}_{\ell m k n}}{dt} \right\rangle_{\text{GW}}^{\text{H}}, \quad (4.2)$$

$$\left\langle \frac{d\mathcal{E}_{\ell m k n}}{dt} \right\rangle_{\text{GW}}^{\infty} \equiv \frac{\mu^{-1}}{4\pi\omega_{mkn}^2} \left| \tilde{Z}_{\ell m k n}^{\infty} \right|^2, \quad (4.3)$$

$$\left\langle \frac{d\mathcal{E}_{\ell m k n}}{dt} \right\rangle_{\text{GW}}^{\text{H}} \equiv \frac{\mu^{-1}\alpha_{\ell m k n}}{4\pi\omega_{mkn}^2} \left| \tilde{Z}_{\ell m k n}^{\text{H}} \right|^2, \quad (4.4)$$

where n_0 is the minimum integer such that $m\Upsilon_{\phi} + k\Upsilon_{\theta} + n_0\Upsilon_r > 0$ holds for each m and k . We also define the intermediate modal energy flux for later use:

$$\left\langle \frac{d\mathcal{E}_{\ell}}{dt} \right\rangle_{\text{GW}}^{\infty} \equiv 2 \sum_{m=-\ell}^{\ell} \sum_{k=-\infty}^{\infty} \sum_{n=n_0}^{\infty} \left\langle \frac{d\mathcal{E}_{\ell m k n}}{dt} \right\rangle_{\text{GW}}^{\infty}, \quad (4.5)$$

$$\left\langle \frac{d\mathcal{E}_{\ell m k}}{dt} \right\rangle_{\text{GW}}^{\infty} \equiv 2 \sum_{n=n_0}^{\infty} \left\langle \frac{d\mathcal{E}_{\ell m k n}}{dt} \right\rangle_{\text{GW}}^{\infty}, \quad (4.6)$$

$$\left\langle \frac{d\mathcal{E}_{\ell}}{dt} \right\rangle_{\text{GW}}^{\text{H}} \equiv 2 \sum_{m=-\ell}^{\ell} \sum_{k=-\infty}^{\infty} \sum_{n=n_0}^{\infty} \left\langle \frac{d\mathcal{E}_{\ell m k n}}{dt} \right\rangle_{\text{GW}}^{\text{H}}, \quad (4.7)$$

$$\left\langle \frac{d\mathcal{E}_{\ell m k}}{dt} \right\rangle_{\text{GW}}^{\text{H}} \equiv 2 \sum_{n=n_0}^{\infty} \left\langle \frac{d\mathcal{E}_{\ell m k n}}{dt} \right\rangle_{\text{GW}}^{\text{H}}, \quad (4.8)$$

The behavior of the spectrum in terms of n is complicated. In Fig. 3, we show the modal energy flux at infinity, $\langle d\mathcal{E}_{\ell m k n}/dt \rangle_{\text{GW}}^{\infty}$, as functions of n in the Schwarzschild case and in the cases of $e = 0.1, 0.5, 0.7$ and 0.9 . Figure 4 is the same figure in the Kerr case with $a = 0.9M$. From these figures, we find that the number of peaks of $\langle d\mathcal{E}_{\ell m k n}/dt \rangle_{\text{GW}}^{\infty}$ is roughly ℓ , and that the value of n at the highest peak of $\langle d\mathcal{E}_{\ell m k n}/dt \rangle_{\text{GW}}^{\infty}$ becomes larger as either ℓ or the eccentricity e becomes larger. For example, the location of the peak of $\langle d\mathcal{E}_{\ell m k n}/dt \rangle_{\text{GW}}^{\infty}$ is approximately $n = 700$ when $e = 0.9$, $\ell = m = 20$ and $k = 0$. The shapes of the spectra in the Schwarzschild and Kerr cases are qualitatively very similar.

In practical computations, we have to truncate the mode summation. We set the target accuracy of the mode summation with respect to n and k to be 10^{-10} . It is useful if we know the location of the highest peak of $\langle d\mathcal{E}_{\ell m k n}/dt \rangle_{\text{GW}}^{\infty}$ before the computation to reduce the computational time. However, it is difficult to derive an analytical expression for such a location. In this work, we adopt the following procedure to determine the range of the n -mode summation. First, we compute $\langle d\mathcal{E}_{\ell m k n}/dt \rangle_{\text{GW}}^{\infty}$ for $\ell = m = 2$ and $k = 0$ for a wide range of n starting from $n = n_0$ to obtain sufficient coverage of the n -mode. In this computation, we obtain the location of the peak $n = n_p$ for $\ell = m = 2$ and $k = 0$. For other $\ell = 2$ modes, since it is expected that the peak value of n is not significantly different from that for $\ell = m = 2$ and $k = 0$, we first search for the peak near n_p . We then compute $\langle d\mathcal{E}_{\ell m k n}/dt \rangle_{\text{GW}}^{\infty}$ starting from the new peak of n , and sum $\langle d\mathcal{E}_{\ell m k n}/dt \rangle_{\text{GW}}^{\infty}$ until the total flux converges with an accuracy of 10^{-10} . For modes (ℓ, m, k) with $\ell > 2$, we basically repeat

the above procedure. We search for the peak near the peak for $(\ell, m, k) = (\ell - 1, \ell - 1, 0)$. Starting from this location of n , we compute and sum $\langle d\mathcal{E}_{\ell m k n} / dt \rangle_{\text{GW}}^\infty$ until the total flux converges.

We show the spectrum of $\langle d\mathcal{E}_{\ell m k} / dt \rangle_{\text{GW}}^\infty$ as functions of k in Figs. 5 and 6 in the Schwarzschild case, and in Figs. 7 and 8 in the Kerr case with $a = 0.9M$. Figures 5 and 7 show the spectrum for the inclination angle $\theta_{\text{inc}} = 20^\circ$, and Figs. 6 and 8 show the spectrum for the high inclination angles $\theta_{\text{inc}} = 70^\circ$ and 80° , respectively. We find that the peak of the k -mode usually exists at approximately $\ell - m$ except for the $m < 0$ modes in the case of a low inclination angle. We also find that when the inclination angle is 20° , the peak value of the modal energy flux becomes smaller when m changes from ℓ to $-\ell$. On the other hand, when the inclination angle is large, i.e., $\theta_{\text{inc}} = 70^\circ$ or 80° , the peak value is largest when $m = 0$. Similarly to the n -mode, the difference between the Schwarzschild and Kerr cases is not very large, but the spectra of the Kerr cases are broader than those of the Schwarzschild cases. By taking this behavior into account, it is straightforward to truncate the k -mode summation, which guarantees the accuracy of the total flux of 10^{-10} .

In Figs. 9 and 10, we show the modal energy flux at the horizon, $\langle d\mathcal{E}_{\ell m k n} / dt \rangle_{\text{GW}}^{\text{H}}$, as functions of n . In Figs. 11–14, we show the spectrum of $\langle d\mathcal{E}_{\ell m k} / dt \rangle_{\text{GW}}^{\text{H}}$ as functions of k . We find that the shape of the energy spectrum at the horizon is very similar to that at infinity. We thus follow the above procedure to determine the range of summation of k and n for the energy spectrum at the horizon.

For the m -mode, we compute all m -modes from ℓ to $-\ell$. For ℓ -mode, we set the maximum of ℓ to be $\ell_{\text{max}} = 20$. This value is chosen to reduce computation time. Since the energy flux for each ℓ -mode monotonically decreases with increasing ℓ , the relative error of the total flux due to this truncation is estimated as

$$\Delta_{(\ell_{\text{max}})}^{\infty, \text{H}} \equiv \left\langle \frac{d\mathcal{E}_{\ell_{\text{max}}}}{dt} \right\rangle_{\text{GW}}^{\infty, \text{H}} / \sum_{\ell=2}^{\ell_{\text{max}}} \left\langle \frac{d\mathcal{E}_{\ell}}{dt} \right\rangle_{\text{GW}}^{\infty, \text{H}}. \quad (4.9)$$

4.2. Rates of change of the three constants of motion

We first show the results of the rate of change of energy and the energy spectrum in the case of a Schwarzschild black hole. Indeed, the Schwarzschild cases are useful for verifying the accuracy of our code. In these cases, the total energy flux after summing the ℓ -, m -, k - and n -modes is independent of the inclination angle. We verify this property by computing the rate of change of energy when the particle moves on the plane with an inclination angle from the equatorial plane around a Schwarzschild black hole. In Table I, we show the data for different inclination angles and eccentricities. We find that, even if the inclination angle is changed, $\langle d\mathcal{E} / dt \rangle^\infty$ remains within the accuracy of $10^{-8} - 10^{-10}$. In this table, truncation

Fig. 3. Modal energy flux $\langle d\mathcal{E}_{\ell m k n}/dt \rangle_{\text{GW}}^\infty$ at infinity for $k = 0$ and $(p, \theta_{\text{inc}}) = (10M, 20^\circ)$ in the Schwarzschild case. The eccentricities are 0.1 (top left), 0.5 (top right), 0.7 (bottom left) and 0.9 (bottom right).

errors $\Delta_{(\ell_{\text{max}})}^\infty$ are shown in square brackets. $\Delta_{(\ell_{\text{max}})}^\infty$ is similar to the truncation errors of n - and k -modes, 10^{-10} . Thus, the errors in Table I are consistent with the truncation errors of the summation of the ℓ -, n - and k -mode.

In Table II, we show similar results for the horizon flux. In these cases, the truncation error from the ℓ -mode summation is negligible. The relative error in Table II is due to the truncation of the n - and k -mode summation.

In Table III, we show the rates of change of the three constants of motion due to the emission of gravitational waves to infinity in the case of various bound orbits around a Kerr black hole with $a = 0.9M$. In this table, we use the same orbital parameters as those used by Drasco and Hughes in Ref. 21). Our results are consistent with theirs except for the rates of change of the Carter constant, $\langle dC/dt \rangle$. This is because they used formulas for $\langle dC/dt \rangle$ under the approximation that the inclination angle does not change. Of course, this holds only approximately. This is the first time that the rate of change of the Carter constant has been computed accurately using an adiabatic approximation. In Table. III, we also show results for the highly eccentricity of $e = 0.9$. In Fig. 15, we plot a highly eccentric orbit with $e = 0.9$, $p = 6M$ and $\theta_{\text{inc}} = 20^\circ$. As indicated in the bottom right figure in Fig. 4, the peak location of the n -mode is approximately 600 when $\ell = m = 20$ and $k = 0$.

The values in the square brackets in Table III are the truncation errors $\Delta_{(\ell_{\text{max}})}^\infty$, which

Fig. 4. Modal energy flux $\langle d\mathcal{E}_{\ell m k n}/dt \rangle_{\text{GW}}^\infty$ at infinity in the Kerr case ($a = 0.9M$) for $k = 0$ and $(p, \theta_{\text{inc}}) = (6M, 20^\circ)$. The eccentricities are 0.1 (top left), 0.5 (top right), 0.7 (bottom left) and 0.9 (bottom right).

take values from 10^{-11} to 10^{-6} . For highly eccentric cases, $e > 0.5$, $\Delta_{(\ell_{\text{max}})}$ is larger than the truncation error of the n - and k -mode summation. Thus, the accuracy for such cases is only limited by the truncation of the ℓ -mode summation. For $e < 0.5$, the truncation errors of the ℓ -mode summation and n - and k -mode summation are comparable, and both errors contribute to the error of the total flux.

In Table IV, we show the time-averaged rates of change of the three constants of motion, $\langle d\mathcal{E}/dt \rangle^{\text{H}}$, $\langle d\mathcal{L}_z/dt \rangle^{\text{H}}$ and $\langle d\mathcal{C}/dt \rangle^{\text{H}}$, due to the absorption at the horizon for various bound orbits around a Kerr black hole. The orbital parameters used here are again the same as those used by Drasco and Hughes in Ref. 21) except for when $e = 0.9$. Our results are consistent with theirs except for the rate of change of the Carter constant. As in the case of Table III, this is the first time that the rate of change of the Carter constant due to absorption by the black hole has been computed accurately using an adiabatic approximation. The cases when $e = 0.9$ are also new results of this work. The numbers in square brackets are the truncation errors of the ℓ -mode summation, $\Delta_{(\ell_{\text{max}})}$, with $\ell_{\text{max}} = 20$. The truncation error of the ℓ -mode summation is much smaller than that of the n - and k -mode summation, which is approximately 10^{-10} . The accuracy of the data in Table IV is limited by the truncation of the n - and k -mode summation.

Here, we discuss the sign of $\langle d\mathcal{E}/dt \rangle^{\text{H}}$. From Table IV, we find that the particle loses

Fig. 5. Modal energy flux $\langle d\mathcal{E}_{\ell mk}/dt \rangle_{\text{GW}}^\infty$ at infinity in the Schwarzschild case. $(p, e, \theta_{\text{inc}}) = (10M, 0.7, 20^\circ)$. $\ell = 2$ (top left), $\ell = 3$ (top right), $\ell = 4$ (bottom left) and $\ell = 5$ (bottom right). These figures show that the peaks are located at approximately $k = \ell - m$.

energy, i.e., $\langle d\mathcal{E}/dt \rangle^{\text{H}} < 0$, when $e = 0.3, 0.5$ and 0.7 and $\theta_{\text{inc}} = 80^\circ$, whereas the particle gains energy, i.e., $\langle d\mathcal{E}/dt \rangle^{\text{H}} > 0$, in the other cases when the eccentricity or the inclination angle is small. From Eq. (2.35), we find that the sign of each mode $\langle d\mathcal{E}/dt \rangle_{\ell mkn}^{\text{H}}$ is determined by the sign of $\alpha_{\ell mkn}$, i.e., $P = \omega_{mkn} - ma/(2Mr_+) = k\Omega_\theta + n\Omega_r - m(a/(2Mr_+) - \Omega_\phi)$. The sign of $\langle d\mathcal{E}/dt \rangle^{\text{H}}$ is determined by the sign of each $\alpha_{\ell mkn}$ and the absolute value of $\langle d\mathcal{E}/dt \rangle_{\ell mkn}^{\text{H}}$. For $a > 0$ (corotation of the particle and the black hole), when a is large and the modes with $m > 0$ and small k and n dominate the total energy flux, the particle can gain energy. We find from Figs. 10 and 13 that when the eccentricity and inclination angle are small, the mode with $\ell = m = 2$ and $k = 0$ dominates the total energy flux and the particle gains energy. On the other hand, when the eccentricity and inclination angle are large, we find from Figs. 10 and 14 that modes with large k and n , which result in $P > 0$, contribute to the total energy flux. Furthermore, Fig. 14 shows that the peak value of $m < 0$ modes is very similar to that for $m > 0$. This also contributes to making $\langle d\mathcal{E}/dt \rangle^{\text{H}}$ positive in the cases of large eccentricity and a large inclination angle.

To confirm the accuracy of the numerical code, we compare our results with the analytical post-Newtonian formulas for orbits that are slightly eccentric but highly inclined.²⁰⁾ We show the results for $p = 100M$ and various e and θ_{inc} in Table V. We find that our numerical

Fig. 6. Modal energy flux $\langle d\mathcal{E}_{\ell mk}/dt \rangle_{\text{GW}}^\infty$ at infinity in the Schwarzschild case. $(p, e, \theta_{\text{inc}}) = (10M, 0.7, 70^\circ)$. $\ell = 2$ (top left), $\ell = 4$ (top right), $\ell = 6$ (bottom left) and $\ell = 8$ (bottom right). These figures show that the peaks are located at approximately $k = \ell - m$.

results and the post-Newtonian formulas agree with an accuracy of $\sim 10^{-4}$ or better. Note that when p is smaller than $100M$, the accuracy of the post-Newtonian formulas becomes worse than this value.

Once we have the rates of change of the constants of motion $I^i = (\mathcal{E}, \mathcal{L}_z, \mathcal{C})$, we can derive the rate of change of the orbital elements $\iota^i = (p, e, \theta_{\text{inc}})$. We have the following relation,

$$\left\langle \frac{d\iota^i}{dt} \right\rangle = (G^{-1})^i_j \left\langle \frac{dI^j}{dt} \right\rangle, \quad (4.10)$$

where $G^i_j = \partial I^i / \partial \iota^j$. In Table VI, we compare $\langle d\iota^i/dt \rangle^\infty$ with values derived using the post-Newtonian formulas by applying Eq. (4.10) to the data in Table V. The relative errors of $\langle dp/dt \rangle^\infty$ and $\langle de/dt \rangle^\infty$ are 10^{-4} , whereas the relative error of $\langle d\theta_{\text{inc}}/dt \rangle^\infty$ is approximately 10^{-2} . This is because in Ref. 20), $\langle d\theta_{\text{inc}}/dt \rangle^\infty$ is derived only up to 1PN order from the leading order, whereas $\langle dp/dt \rangle$ and $\langle de/dt \rangle$ are derived up to 2.5PN order.

We apply Eq. (4.10) to the data in Tables III and IV to obtain the rates of change of the orbital elements due to the emission of gravitational waves to infinity and to absorption by the black hole, which are shown in Tables VII and VIII, respectively. We find that in most cases, the flux at infinity and absorption by the black hole exhibit opposite effects except when $e = 0.3, 0.5$ and 0.7 and $\theta_{\text{inc}} = 80^\circ$. In all cases, since the flux at infinity dominates

Fig. 7. Modal energy flux $\langle d\mathcal{E}_{\ell mk}/dt \rangle_{\text{GW}}^{\infty}$ at infinity in the Kerr case ($a = 0.9M$). $(p, e, \theta_{\text{inc}}) = (6M, 0.7, 20^\circ)$. $\ell = 2$ (top left), $\ell = 3$ (top right), $\ell = 4$ (bottom left) and $\ell = 5$ (bottom right). These figures show that the peaks are located at approximately $k = \ell - m$.

the sign of the total rate of change, the total rates of change shown in Table IX have the same sign as those for infinity.

To demonstrate some aspects of the evolution of the orbital elements, in Figs. 16 and 17 we plot the total rates of change $(\langle dp/dt \rangle, \langle d\theta_{\text{inc}}/dt \rangle)$ and $(\langle dp/dt \rangle, \langle de/dt \rangle)$ on the (p, θ_{inc}) and (p, e) planes, respectively, in the case when $a = 0.9M$ and $\ell_{\text{max}} = 5$. We find that although the eccentricity is always decreasing at large p , it can increase near the last stable orbit (LSO). The change in the inclination angle is not very significant in the figures, but it is always increasing at large p .

Fig. 8. Modal energy flux $\langle d\mathcal{E}_{\ell m k}/dt \rangle_{\text{GW}}^{\infty}$ at infinity in the Kerr case ($a = 0.9M$). $(p, e, \theta_{\text{inc}}) = (6M, 0.7, 80^\circ)$. $\ell = 2$ (top left), $\ell = 4$ (top right), $\ell = 6$ (bottom left) and $\ell = 8$ (bottom right). These figures show that the peaks are located at approximately $k = \ell - m$.

Fig. 9. Modal energy flux $|\langle d\mathcal{E}_{\ell m k n}/dt \rangle_{\text{GW}}^{\text{H}}|$ at the horizon for $k = 0$ and $(p, \theta_{\text{inc}}) = (10M, 20^\circ)$ in the Schwarzschild case. The eccentricities are 0.1 (top left), 0.5 (top right), 0.7 (bottom left) and 0.9 (bottom right).

Fig. 10. Modal energy flux $|\langle d\mathcal{E}_{\ell m k n}/dt \rangle_{\text{GW}}^{\text{H}}|$ at the horizon in the Kerr case ($a = 0.9M$) for $k = 0$ and $(p, \theta_{\text{inc}}) = (6M, 20^\circ)$. The eccentricities are 0.1 (top left), 0.5 (top right), 0.7 (bottom left) and 0.9 (bottom right).

Fig. 11. Modal energy flux $|\langle d\mathcal{E}_{\ell m k}/dt \rangle_{\text{GW}}^{\text{H}}|$ at the horizon in the Schwarzschild case. $(p, e, \theta_{\text{inc}}) = (10M, 0.7, 20^\circ)$. $\ell = 2$ (top left), $\ell = 3$ (top right), $\ell = 4$ (bottom left) and $\ell = 5$ (bottom right). These figures show that the peaks are located at approximately $k = \ell - m$.

Fig. 12. Modal energy flux $|\langle d\mathcal{E}_{\ell m k}/dt \rangle_{\text{GW}}^{\text{H}}|$ at the horizon in the Schwarzschild case. $(p, e, \theta_{\text{inc}}) = (10M, 0.7, 70^\circ)$. $\ell = 2$ (top left), $\ell = 4$ (top right), $\ell = 6$ (bottom left) and $\ell = 8$ (bottom right). These figures show that the peaks are located at approximately $k = \ell - m$.

Fig. 13. Modal energy flux $|\langle d\mathcal{E}_{\ell m k}/dt \rangle_{\text{GW}}^{\text{H}}|$ at the horizon in the Kerr case ($a = 0.9M$). $(p, e, \theta_{\text{inc}}) = (6M, 0.7, 20^\circ)$. $\ell = 2$ (top left), $\ell = 3$ (top right), $\ell = 4$ (bottom left) and $\ell = 5$ (bottom right). These figures show that the peaks are located at approximately $k = \ell - m$.

Fig. 14. Modal energy flux $|\langle d\mathcal{E}_{\ell mk}/dt \rangle_{\text{GW}}^{\text{H}}|$ at the horizon in the Kerr case ($a = 0.9M$). $(p, e, \theta_{\text{inc}}) = (6M, 0.7, 80^\circ)$. $\ell = 2$ (top left), $\ell = 4$ (top right), $\ell = 6$ (bottom left) and $\ell = 8$ (bottom right). These figures show that the peaks are located at approximately $k = \ell - m$.

Fig. 15. Plots of the orbits in the same coordinate systems as those used in Fig. 2. This generic geodesic orbit has eccentricity $e = 0.9$, semilatus rectum $p = 6M$ and inclination angle $\theta_{\text{inc}} = 20^\circ$. The spin of the black hole is set to $a = 0.9M$.

Table I. Time-averaged rates of change of the energy of a particle due to the emission of gravitational waves to infinity for the case of a Schwarzschild black hole. In this table, the orbital radius is $10M$. We compare the result for the equatorial plane with that for a nonequatorial plane. Truncation errors $\Delta_{(\ell_{\max})}^{\infty}$ are shown in square brackets. Here we set $\ell_{\max} = 20$. These results show that the error of $\langle d\mathcal{E}/dt \rangle^{\infty}$ is consistent with the truncation error of the mode summation.

a/M	p/M	e	θ_{inc}	$\langle d\mathcal{E}/dt \rangle^{\infty}$	Relative error
0	10	0.1	0°	$-6.31752474720 \times 10^{-5}$	$[10^{-11}]$

Table II. Time-averaged rates of change of the energy of a particle due to the emission of gravitational waves to the horizon for the case of a Schwarzschild black hole. In this table, the orbital radius is $10M$. We compare the result for the equatorial plane with that for a nonequatorial plane. Truncation errors $\Delta_{(\ell_{\max})}^H$ are shown in square brackets. Here we set $\ell_{\max} = 20$.

Table III. Time-averaged rates of change of the three constants of motion, energy $\langle d\mathcal{E}/dt \rangle^\infty$, angular momentum $\langle d\mathcal{L}_z/dt \rangle^\infty$ and the Carter constant $\langle d\mathcal{C}/dt \rangle^\infty$, due to gravitational waves radiated to infinity per unit mass for various generic orbits around a Kerr black hole. The orbital parameters used here are the same as those used by Drasco and Hughes in Ref. 21) except when $e = 0.9$. Our results are consistent with theirs except for the rate of change of the Carter constant, $\langle d\mathcal{C}/dt \rangle^\infty$. Numbers in square brackets are the truncation errors of the ℓ -mode summation, $\Delta_{(\ell_{\max})}$ with $\ell_{\max} = 20$. Note that the case of $a = 0.9M$, $p = 6M$, $e = 0.9$ and $\theta_{\text{inc}} = 80^\circ$ does not result in stable bound orbits.

§5. Summary

In this paper, we developed a numerical code to compute gravitational waves induced by a particle orbiting around a Kerr black hole. We obtained the rates of change of energy, angular momentum and the Carter constant for various eccentric and inclined orbits. This is the first time that the rate of change of the Carter constant has been evaluated accurately. These computations include highly eccentric cases, i.e., $e = 0.9$. In previous works, such high eccentricity was not treated.

Our numerical method is mainly divided into four parts: the computation of the radial and polar motion, the homogeneous solution of the Teukolsky equation, the integration of

Fig. 16. Evolution of eccentric and inclined orbits projected on the $e = \text{const.}$ plane. The black hole spin is $a = 0.9M$. The dashed curves represent the last stable orbit (LSO). Each point represents an orbit and each arrow represents the rate of change of the orbit $(\langle dp/dt \rangle, \langle d\theta_{\text{inc}}/dt \rangle)$. Here, the lengths of arrows are normalized appropriately. The top left and top right figures show the evolution on the $e = 0.1$ and $e = 0.3$ planes respectively. The bottom left and bottom right figures show the evolution on the $e = 0.5$ and $e = 0.7$ planes respectively. At a large distance, p is always decreasing and θ_{inc} is always increasing. In the computation of this figure, we set $\ell_{\text{max}} = 5$.

Eq. (2-32) and the mode summation in Eqs. (2-35)–(2-38). We found that the radial and polar motion can be expressed in terms of Jacobi elliptic functions. This enabled us to solve the geodesic motion more accurately than the method in which the equations of motion are integrated numerically. The asymptotic amplitudes, such as $B_{\ell m \omega}^{\text{inc}}$, can be computed directly from the MST formalism. We do not need to evaluate the homogeneous solutions at a very large distance to obtain the asymptotic amplitudes. We computed the homogeneous Teukolsky solution, $R_{\ell m \omega}^{\text{in}}$, at a radius r between $r_{\text{min}} \leq r \leq r_{\text{max}}$ using the MST formalism accurately. The homogeneous solution at other radial points is computed by successive Taylor series expansions. The Taylor series method gives very high accuracy and is much faster than the use of the hypergeometric function expansion at all radial points. We computed the integral, Eq. (2-32), using the trapezium rule, which gives very high accuracy when periodic functions are integrated over one period.

The accuracy of the numerical results are limited by the truncation of the summation of

Fig. 17. Evolution of eccentric and inclined orbits projected on the $\theta_{\text{inc}} = \text{const.}$ plane. The black hole spin is $a = 0.9M$. The dashed curves represent the last stable orbit (LSO). Each orbit is represented by a point and its evolution is represented by a vector $(\langle dp/dt \rangle, \langle de/dt \rangle)$. The top left figure shows the evolution on the $\theta_{\text{inc}} = 20^\circ$ plane and the top right figure shows the evolution on the $\theta_{\text{inc}} = 40^\circ$ plane. The bottom left figure shows the evolution on the $\theta_{\text{inc}} = 60^\circ$ plane and the bottom right figure shows the evolution on the $\theta_{\text{inc}} = 80^\circ$ plane. At a large distance, p and e are always decreasing. In the computation of this figure, we set $\ell_{\text{max}} = 5$.

the ℓ -, k - and n -modes. We have verified the behavior of the energy spectrum of the k - and n -modes. We determined the range of the summation of k and n to obtain an error due to the truncation of k - and n -modes of less than 10^{-10} . We truncated the ℓ -mode at $\ell = 20$. This value was chosen to reduce computation time. The error due to the truncation of the ℓ -mode depends on the orbital parameters. When the eccentricity is small, i.e. $e < 0.3$, this error is approximately 10^{-9} . However, when the eccentricity is $e = 0.9$, this error becomes 10^{-5} , which is the largest error out of the results computed in this paper. Note that since the error is only limited by the truncation of the ℓ -, k - and n -modes, it is straightforward to improve the accuracy.

To confirm the accuracy of our code, we computed the energy flux from a Schwarzschild black hole for cases when the orbits are inclined with respect to the equatorial plane. In the Schwarzschild case, the energy flux should not depend on the inclination angle. Thus, we can estimate the accuracy of the code by comparing the results for inclined orbits and equatorial orbits. We found that the accuracy of our code is consistent with the estimates

Table VII. Time-averaged rates of change of orbital elements, semilatus rectum $\langle dp/dt \rangle^\infty$, eccentricity $\langle de/dt \rangle^\infty$ and inclination angle $\langle d\theta_{\text{inc}}/dt \rangle^\infty$ due to gravitational waves radiated to infinity per unit mass for various generic orbits around a Kerr black hole. The orbital parameters used here are the same as those used in Tables III and IV. Here we set $\ell_{\text{max}} = 20$. Note that the case of $q = 0.9M$, $p = 6M$, $e = 0.9$ and $\theta_{\text{inc}} = 80^\circ$ does not result in stable bound orbits.

of the truncation errors of the ℓ -, k - and n -modes.

Although we have not completely optimized the code, we briefly discuss the computation time here. In the current code, the computation time for one mode is roughly 0.1 – 0.3 seconds. The total computation time is about 6 – 12 hours when $q = 0.9, p = 6M, e = 0.1$ and $\theta_{\text{inc}} = 20^\circ - 80^\circ$, about 1 day when $q = 0.9, p = 6M, e = 0.7$ and $\theta_{\text{inc}} = 20^\circ - 80^\circ$, and 1 – 3 days when $q = 0.9, p = 6M, e = 0.9$ and $\theta_{\text{inc}} = 20^\circ - 60^\circ$. These times are for the results of computation with one 2.5 GHz AMD Opteron CPU. In Fig.1 in Ref. 14), the computation time for one mode is shown. The computation time using 8 CPUs is about 0.4 seconds when $q = 0.7, p = 10M, e = 0.5$ and $\theta_{\text{inc}} = 45^\circ$. Thus, the computation time using one CPU will be a few seconds. Thus, our computation time appears to be much shorter than that in Ref.14).

By optimizing the code, we can further increase its speed. Also, it is possible to consider

Table VIII. Time-averaged rates of change of orbital elements, semilatus rectum $\langle dp/dt \rangle^H$, eccentricity $\langle de/dt \rangle^H$ and inclination angle $\langle d\theta_{\text{inc}}/dt \rangle^H$ due to absorption by a black hole per unit mass for various generic orbits around a Kerr black hole. The orbital parameters used here are the same as those used in Tables III and IV. Here we set $\ell_{\text{max}} = 20$. Note that the case of $q = 0.9M$, $p = 6M$, $e = 0.9$ and $\theta_{\text{inc}} = 80^\circ$ does not result in stable bound orbits. $\langle dp/dt \rangle^H$ and $\langle d\theta_{\text{inc}}/dt \rangle^H$ have opposite signs to $\langle dp/dt \rangle^\infty$ and $\langle d\theta_{\text{inc}}/dt \rangle^\infty$ respectively. $\langle de/dt \rangle^H$ also has the opposite sign to $\langle de/dt \rangle^\infty$ except when $\theta_{\text{inc}} = 80^\circ$.

variants of the method used to obtain the homogeneous solutions, the orbital motion, and so forth. Although we have not used numerical integration methods, it may be advantageous to use them under some circumstances. We will consider these issues in the future. We will also investigate the computation of gravitational waves including the effects of the adiabatic evolution of a particle orbit due to the emission of gravitational waves. This is important for investigating EMRI through the data analysis of LISA. We will also investigate the possibility of computation over a wider range of orbital parameters, such as an eccentricity larger than 0.9, and an inclination angle of $\theta = 90^\circ$.

We are planning to make our code available to the public so that a wide range of people may use it. We believe our code will be very useful for investigating astrophysical and data analysis issues of EMRI and for analyzing the data obtained from LISA, DECIGO and BBO.

Table IX. Total time-averaged rates of change of orbital elements, semilatus rectum $\langle dp/dt \rangle$, eccentricity $\langle de/dt \rangle$ and inclination angle $\langle d\theta_{\text{inc}}/dt \rangle$ due to gravitational waves per unit mass for various generic orbits around a Kerr black hole. The values in this table are the sums of the values in Tables VII and VIII.

—— Explicit Expressions for $Z_{\ell m \omega}^{\infty}$ and $Z_{\ell m \omega}^H$ ——

In this section, we give explicit expressions for the amplitude of the partial waves $Z_{\ell m \omega}^{H/\infty}$.

Using the Green function of the radial Teukolsky equation, the solutions of the Teukolsky equation are expressed as

$$R_{\ell m \omega}(r) = R_{\ell m \omega}^{\text{up}}(r)Z_{\ell m \omega}^{\infty}(r) + R_{\ell m \omega}^{\text{in}}(r)Z_{\ell m \omega}^H(r), \quad (\text{A.1})$$

where $R_{\ell m \omega}^{\text{in/up}}(r)$ satisfy ingoing/outgoing wave conditions at the horizon/infinity, and

$$\begin{aligned} Z_{\ell m \omega}^{\text{H}} &= \frac{\mu B_{\ell m \omega}^{\text{trans}}}{2i\omega C_{\ell m \omega}^{\text{trans}} B_{\ell m \omega}^{\text{inc}}} \int_{-\infty}^{\infty} dt e^{i\omega t - im\phi(t)} \mathcal{I}_{\ell m \omega}^{\text{H}}[r(t), \theta(t)], \\ Z_{\ell m \omega}^{\infty} &= \frac{\mu}{2i\omega B_{\ell m \omega}^{\text{inc}}} \int_{-\infty}^{\infty} dt e^{i\omega t - im\phi(t)} \mathcal{I}_{\ell m \omega}^{\infty}[r(t), \theta(t)], \end{aligned} \quad (\text{A}\cdot 2)$$

where

$$\begin{aligned} \mathcal{I}_{\ell m \omega}^{\text{H}} &= \left[R_{\ell m \omega}^{\text{up}} \{A_{nn0} + A_{\bar{m}n0} + A_{\bar{m}\bar{m}0}\} \right. \\ &\quad \left. - \frac{dR_{\ell m \omega}^{\text{up}}}{dr} \{A_{\bar{m}n1} + A_{\bar{m}\bar{m}1}\} + \frac{d^2 R_{\ell m \omega}^{\text{up}}}{d^2 r} A_{\bar{m}\bar{m}2} \right]_{r=r(t), \theta=\theta(t)}, \\ \mathcal{I}_{\ell m \omega}^{\infty} &= \left[R_{\ell m \omega}^{\text{in}} \{A_{nn0} + A_{\bar{m}n0} + A_{\bar{m}\bar{m}0}\} \right. \\ &\quad \left. - \frac{dR_{\ell m \omega}^{\text{in}}}{dr} \{A_{\bar{m}n1} + A_{\bar{m}\bar{m}1}\} + \frac{d^2 R_{\ell m \omega}^{\text{in}}}{d^2 r} A_{\bar{m}\bar{m}2} \right]_{r=r(t), \theta=\theta(t)}. \end{aligned} \quad (\text{A}\cdot 3)$$

Here

$$\begin{aligned} A_{nn0} &= \frac{-2}{\sqrt{2\pi} \Delta^2} C_{nn} \rho^{-2} \bar{\rho}^{-1} \mathcal{L}_1^\dagger \left\{ \rho^{-4} \mathcal{L}_2^\dagger (\rho^3 S_{\ell m}^{a\omega}) \right\}, \\ A_{\bar{m}n0} &= \frac{2}{\sqrt{\pi} \Delta} C_{\bar{m}n} \rho^{-3} \left[(\mathcal{L}_2^\dagger S_{\ell m}^{a\omega}) \left(\frac{iK}{\Delta} + \rho + \bar{\rho} \right) - a \sin \theta S_{\ell m}^{a\omega} \frac{K}{\Delta} (\bar{\rho} - \rho) \right], \\ A_{\bar{m}\bar{m}0} &= -\frac{1}{\sqrt{2\pi}} \rho^{-3} \bar{\rho} C_{\bar{m}\bar{m}} S_{\ell m}^{a\omega} \left[-i \left(\frac{K}{\Delta} \right)_{,r} - \frac{K^2}{\Delta^2} + 2i\rho \frac{K}{\Delta} \right], \\ A_{\bar{m}n1} &= \frac{2}{\sqrt{\pi} \Delta} \rho^{-3} C_{\bar{m}n} \left[\mathcal{L}_2^\dagger S_{\ell m}^{a\omega} + ia \sin \theta (\bar{\rho} - \rho) S_{\ell m}^{a\omega} \right], \\ A_{\bar{m}\bar{m}1} &= -\frac{2}{\sqrt{2\pi}} \rho^{-3} \bar{\rho} C_{\bar{m}\bar{m}} S_{\ell m}^{a\omega} \left(i \frac{K}{\Delta} + \rho \right), \\ A_{\bar{m}\bar{m}2} &= -\frac{1}{\sqrt{2\pi}} \rho^{-3} \bar{\rho} C_{\bar{m}\bar{m}} S_{\ell m}^{a\omega}, \end{aligned} \quad (\text{A}\cdot 4)$$

where $\mathcal{L}_\sigma^\dagger \equiv \partial_\theta - m/\sin \theta + a\omega \sin \theta + \sigma \cot \theta$ and

$$\begin{aligned} C_{nn} &\equiv \frac{\rho^2 \bar{\rho}^2}{4\dot{t}} \left[\mathcal{E}(r^2 + a^2) - a\mathcal{L} + \frac{dr}{d\lambda} \right]^2, \\ C_{\bar{m}n} &\equiv -\frac{\rho^2 \bar{\rho}}{2\sqrt{2}\dot{t}} \left[\mathcal{E}(r^2 + a^2) - a\mathcal{L} + \frac{dr}{d\lambda} \right] \left[i \sin \theta \left(a\mathcal{E} - \frac{\mathcal{L}}{\sin^2 \theta} \right) - \frac{1}{\sin \theta} \frac{d \cos \theta}{d\lambda} \right], \\ C_{\bar{m}\bar{m}} &\equiv \frac{\rho^2}{2\dot{t}} \left[i \sin \theta \left(a\mathcal{E} - \frac{\mathcal{L}}{\sin^2 \theta} \right) - \frac{1}{\sin \theta} \frac{d \cos \theta}{d\lambda} \right]^2. \end{aligned} \quad (\text{A}\cdot 5)$$

Appendix B

— Geodesic Motion in the Kerr Spacetime —

In this section, we discuss the solutions of the geodesic equations in detail. First, we describe analytical solutions of the r and θ components of the geodesic equations, which are

expressed as

$$\left(\frac{dr}{d\lambda}\right)^2 = R(r), \quad (\text{B}\cdot 1)$$

$$\left(\frac{d\cos\theta}{d\lambda}\right)^2 = \Theta(\cos\theta), \quad (\text{B}\cdot 2)$$

where

$$\begin{aligned} P(r) &= \mathcal{E}(r^2 + a^2) - a\mathcal{L}_z, \\ R(r) &= [P(r)]^2 - \Delta[r^2 + (a\mathcal{E} - \mathcal{L}_z)^2 + \mathcal{C}], \\ \Theta(\cos\theta) &= \mathcal{C} - (\mathcal{C} + a^2(1 - \mathcal{E}^2) + \mathcal{L}_z^2)\cos^2\theta + a^2(1 - \mathcal{E}^2)\cos^4\theta. \end{aligned}$$

Since $R(r)$ and $\Theta(\cos\theta)$ are fourth-order polynomials, there are four zeros of r and $\cos\theta$ for each function, respectively. A geodesic can be specified if we set two zero points, $r_{\min}$ and $r_{\max}$, for the radial part and one zero point, $\cos\theta_{\min}$, for the polar part. This corresponds to the fact that a one-to-one correspondence exists between $(r_{\min}, r_{\max}, \theta_{\min})$ and $(\mathcal{E}, \mathcal{L}_z, \mathcal{C})$.

It is convenient to introduce the orbital parameters, eccentricity e , semilatus rectum p and inclination angle θ_{inc} , defined as

$$r_{\min} = \frac{p}{1+e}, \quad r_{\max} = \frac{p}{1-e}, \quad \theta_{\text{inc}} + (\text{sgn } \mathcal{L}_z) \theta_{\min} = \frac{\pi}{2}. \quad (\text{B}\cdot 3)$$

The three constants of motion, $(\mathcal{E}, \mathcal{L}_z, \mathcal{C})$, are expressed in terms of these orbital parameters $(p, e, \theta_{\text{inc}})$.^{21), 28)}

To solve the differential equations for r and $\cos\theta$, we rewrite $R(r)$ and $\Theta(\cos\theta)$ as

$$\begin{aligned} R(r) &= (1 - \mathcal{E}^2)(r_1 - r)(r - r_2)(r - r_3)(r - r_4), \\ \Theta(\cos\theta) &= \mathcal{L}_z^2 \epsilon_0 (z_- - \cos^2\theta)(z_+ - \cos^2\theta), \end{aligned}$$

where

$$\begin{aligned} r_1 &= \frac{p}{1-e}, \quad r_2 = \frac{p}{1+e}, \quad r_3 = \frac{(A+B) + \sqrt{(A+B)^2 - 4AB}}{2}, \quad r_4 = \frac{AB}{r_3}, \\ A+B &= \frac{2}{1-\mathcal{E}^2} - (r_1 + r_2), \quad AB = \frac{a^2\mathcal{C}}{(1-\mathcal{E}^2)r_1r_2}, \end{aligned} \quad (\text{B}\cdot 4)$$

and $\epsilon_0 = a^2(1 - \mathcal{E}^2)/\mathcal{L}_z^2$, $z_- = \cos^2\theta_{\min}$, $z_+ = \mathcal{C}/(\mathcal{L}_z^2\epsilon_0 z_-)$.

Let the solutions of Eqs. (B.1) and (B.2) in terms of r or θ be $\lambda^{(r)}(r)$ and $\lambda^{(\theta)}(\theta)$, respectively. The functions $\lambda^{(r)}(r)$ and $\lambda^{(\theta)}(\theta)$ are expressed as

$$\lambda^{(r)}(r) = \begin{cases} \lambda_0^{(r)}(r) & r : r_2 \rightarrow r_1, \\ 2\lambda_0^{(r)}(r_1) - \lambda_0^{(r)}(r) & r : r_1 \rightarrow r_2, \end{cases}$$

$$\lambda^{(\theta)}(\theta) = \begin{cases} \lambda_0^{(\theta)}(\theta) & \theta : \frac{\pi}{2} \rightarrow \theta_{\min}, \\ 2\lambda_0^{(\theta)}(\theta_{\min}) - \lambda_0^{(\theta)}(\theta) & \theta : \theta_{\min} \rightarrow \pi - \theta_{\min}, \\ 4\lambda_0^{(\theta)}(\theta_{\min}) + \lambda_0^{(\theta)}(\theta) & \theta : \pi - \theta_{\min} \rightarrow \frac{\pi}{2}, \end{cases} \quad (\text{B}\cdot 5)$$

where

$$\begin{aligned} \lambda_0^{(r)}(r) &= \frac{1}{\sqrt{1-\mathcal{E}^2}} \frac{2}{\sqrt{(r_1-r_3)(r_2-r_4)}} F\left(\arcsin \sqrt{\frac{r_1-r_3}{r_1-r_2} \frac{r-r_2}{r-r_3}}, \sqrt{\frac{r_1-r_2}{r_1-r_3} \frac{r_3-r_4}{r_2-r_4}}\right), \\ \lambda_0^{(\theta)}(\theta) &= \frac{1}{\mathcal{L}_z \sqrt{\epsilon_0 z_+}} F\left(\arcsin \frac{\cos \theta}{\sqrt{z_-}}, \sqrt{\frac{z_-}{z_+}}\right), \end{aligned} \quad (\text{B}\cdot 6)$$

and the function F is an elliptic integral of the first kind. In the following, we describe the elliptic integrals and functions using the notation in Ref. 30).

The orbital frequencies of the radial and polar motion with respect to λ , which are denoted by Υ_r and Υ_θ , respectively, are defined in (2\cdot 18). They are expressed as

$$\Upsilon_r = \frac{\pi \sqrt{(1-\mathcal{E}^2)(r_1-r_3)(r_2-r_4)}}{2K(k_r)}, \quad \Upsilon_\theta = \frac{\pi \mathcal{L}_z \sqrt{\epsilon_0 z_+}}{2K(k_\theta)}. \quad (\text{B}\cdot 7)$$

Here $K(k)$ is the complete elliptic integral of the first kind, and

$$k_r = \sqrt{\frac{r_1-r_2}{r_1-r_3} \frac{r_3-r_4}{r_2-r_4}}, \quad k_\theta = \sqrt{\frac{z_-}{z_+}}. \quad (\text{B}\cdot 8)$$

Furthermore, Eq. (B\cdot 5) can be solved inversely.

$$r(w_r) = \frac{r_3(r_1-r_2) \text{sn}^2(\varphi_r(w_r); k_r) - r_2(r_1-r_3)}{(r_1-r_2) \text{sn}^2(\varphi_r(w_r); k_r) - (r_1-r_3)}, \quad [\cos \theta](w_\theta) = \sqrt{z_-} \text{sn}(\varphi_\theta(w_\theta); k_\theta). \quad (\text{B}\cdot 9)$$

For convenience, we have introduced the angle variables,

$$w_r = \Upsilon_r \lambda, \quad w_\theta = \Upsilon_\theta \lambda. \quad (\text{B}\cdot 10)$$

The function $\text{sn}(\varphi, k)$ (and $\text{cn}(\varphi, k)$ and $\text{dn}(\varphi, k)$ below) is a Jacobi elliptic function and

$$\begin{aligned} \varphi_r(w_r) &= \begin{cases} w_r \frac{K(k_r)}{\pi}, & (0 \leq w_r \leq \pi) \\ (2\pi - w_r) \frac{K(k_r)}{\pi}, & (\pi \leq w_r \leq 2\pi) \end{cases} \\ \varphi_\theta(w_\theta) &= \begin{cases} w_\theta \frac{2K(k_\theta)}{\pi}, & (0 \leq w_\theta \leq \frac{\pi}{2}) \\ (\pi - w_\theta) \frac{2K(k_\theta)}{\pi}, & (\frac{\pi}{2} \leq w_\theta \leq \frac{3\pi}{2}) \\ (w_\theta - 2\pi) \frac{2K(k_\theta)}{\pi}, & (\frac{3\pi}{2} \leq w_\theta \leq \pi) \end{cases} \end{aligned} \quad (\text{B}\cdot 11)$$

By differentiating r and $\cos \theta$ with respect to λ , we respectively obtain $dr/d\lambda$ and $d \cos \theta/d\lambda$ analytically, which are expressed as

$$\begin{aligned} \left[\frac{dr}{d\lambda} \right] (w_r) &= 2 \operatorname{sgn} \left(\frac{d\varphi_r}{dw_r} \right) \\ &\quad \times \frac{\operatorname{sn}(\varphi_r; k_r) \operatorname{cn}(\varphi_r; k_r) \operatorname{dn}(\varphi_r; k_r) (r_2 - r_3) (r_1 - r_3) (r_1 - r_2) K(k_r) \Upsilon_r}{((r_1 - r_2) \operatorname{sn}^2(\varphi_r; k_r) - (r_1 - r_3))^2 \pi}, \\ \left[\frac{d \cos \theta}{d\lambda} \right] (w_\theta) &= 2 \operatorname{sgn} \left(\frac{d\varphi_\theta}{dw_\theta} \right) \sqrt{z_-} \operatorname{cn}(\varphi_\theta; k_\theta) \operatorname{dn}(\varphi_\theta; k_\theta) \frac{K(k_\theta) \Upsilon_\theta}{\pi}, \end{aligned} \quad (\text{B.12})$$

where

$$\operatorname{sgn}(x) = \begin{cases} 1 & \text{for } x > 0, \\ 0 & \text{for } x = 0, \\ -1 & \text{for } x < 0. \end{cases}$$
